

# Proposal for AGL Sound management

AGL F2F meeting @ San Jose  
July 2017

Naohiro Nishiguchi  
nnishiguchi@jp.adit-jv.com

Advanced Driver  
Information Technology

- I have more than 10 years experiences in IVI product development for Audio domain
  - ◆ Application layer
  - ◆ Middleware (e.g. Media playback engine, Beep playback engine)
  - ◆ Audio routing management to adapt/configure real customer projects
  - ◆ ALSA
- I am audio experts from low-level to high-level application layer covered, and had been working more on customer project.
- Currently, I started more on platform, especially audio routing management framework to be more easily applicable to actual customer projects.

- **Use cases in automotive**
- **System architecture**
- **Requirement for automotive sound management**
- **Comparison between Advanced ALSA audio agent and Genivi Audio manager**
- **Proposal**
- **Sound manager PoC**

### ■ Example Use Cases

#### ◆ Active Source Change

- Driver is listening to Mediaplayer in the car.
- Incoming phone call and answer the phone
- IVI system **automatically** pause Mediaplayer, and then play Phone sound.
- After Phone call is completed, IVI system **automatically** resume play Mediaplyer

#### ◆ Last Audio (Persistence)

- Driver is listening to Radio in the car.
- Driver turns off/on the engine.
- IVI system **automatically** start playing Radio.

#### ◆ Mixing & Volume Attenuation

- Driver is listening to Radio in the car.
- Car detect moving objects when parking.
- IVI system **automatically** mute(or reduce)the volume of Radio, and then start playing Alarm using another speaker.
- After Alarm is completed, IVI system **automatically** recover the volume level of Radio.

**Implicit policy management is required**

- There are several Hardware architectures as presented by MAZDA in ALS 2017

### ■ Compact

- ◆ There are several communication protocols between SoC and others.
- ◆ Sound devices are connected to SoC **directly**.
- ◆ All audio streaming is **visible** and application **can control** audio streaming and volume directly.
  - SoC is master of volume

### ■ Luxury

- ◆ There are several communication protocols between SoC and others.
- ◆ Some sound devices are **NOT** connected to SoC.
- ◆ Some audio streaming is **INVISIBLE** and application **can NOT** control audio streaming and volume. e.g. Meter, Camera to AMP
  - External ECU is master of volume

**Several types of hardware have to be supported**

### ■ Requirement mapping

#### use cases & system architecture

Active Source Change

Last Audio

Mixing & Volume attenuation

compact

Visible source / sink

Visible streaming

Volume master is SoC

Luxury

Invisible source / sink

Invisible streaming

Volume master is external

Several communication methods

#### Requirements

Shall be able to apply business logic implicitly

Shall have a persistency for sound source and volume.

Shall know all sound sources and sinks in system

Shall manage sound route regardless of source and sink location.

Shall manage volume regardless of the master of volume location.

Shall be able to be used by applications easily.

Shall be extensible (independent from specific routing mechanism to control)

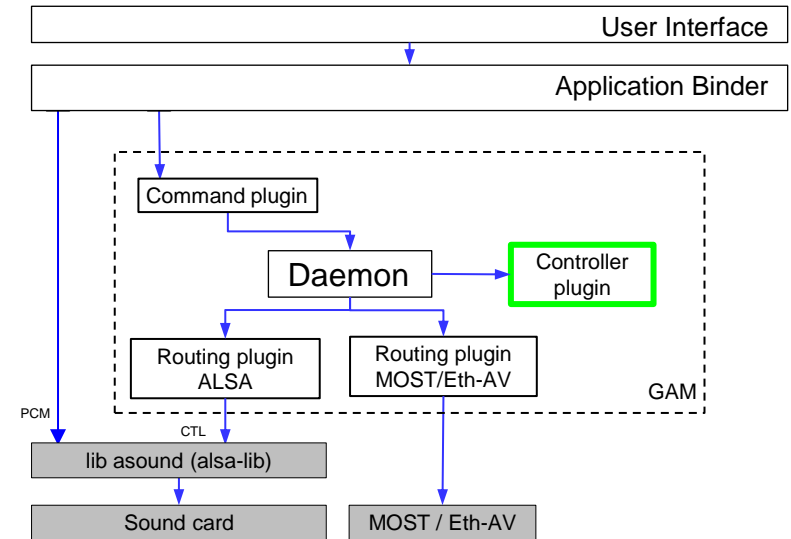

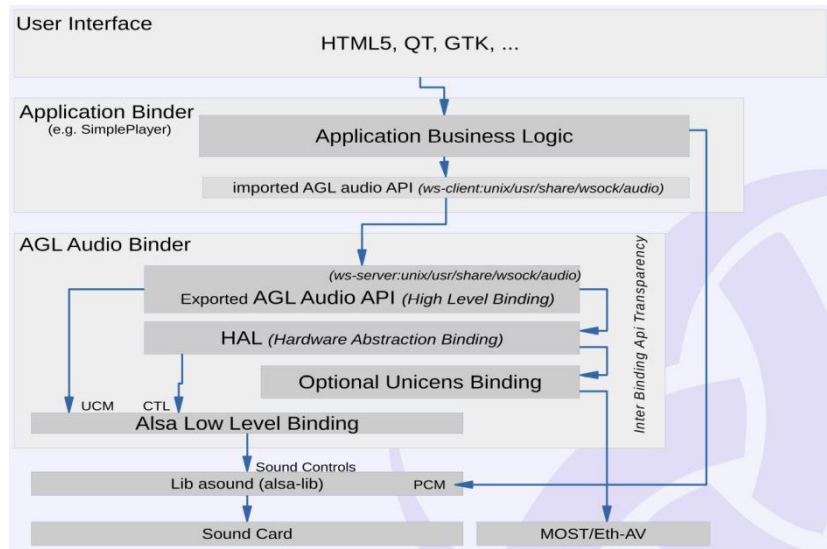

Shall be reliable

## ■ Requirement coverage

| Requirements                                                                 | AAA                                                                | GAM                                                               |
|------------------------------------------------------------------------------|--------------------------------------------------------------------|-------------------------------------------------------------------|
| Shall be able to apply business logic implicitly                             | ???<br>The feasibility of "Pause" is unclear.                      | FEASILBE                                                          |
| Shall have a persistency for sound source and volume.                        | FEASILBE<br>Cooperation with other components is required          | FEASILBE<br>Already exist                                         |
| Shall know all sound sources and sinks in system                             | FEASILBE<br>By dedicated binder                                    | FEASILBE<br>By registration mechanism                             |
| Shall manage sound route regardless of source and sink location.             | FEASILBE<br>Dedicated binding development is required for external | FEASILBE<br>Dedicated plugin development is required for external |
| Shall manage volume regardless of the master of volume location              | ???<br>How to abstract external source?                            | FEASILBE<br>Dedicated plugin development is required for external |
| Shall be able to be used by applications easily.                             | It is general in Linux                                             | It is OSS.                                                        |
| Shall be extensible (independent from specific routing mechanism to control) | Dedicated binding is required                                      | Dedicated plug-in is required                                     |
| Shall be reliable                                                            | Developing                                                         | Already in the market                                             |

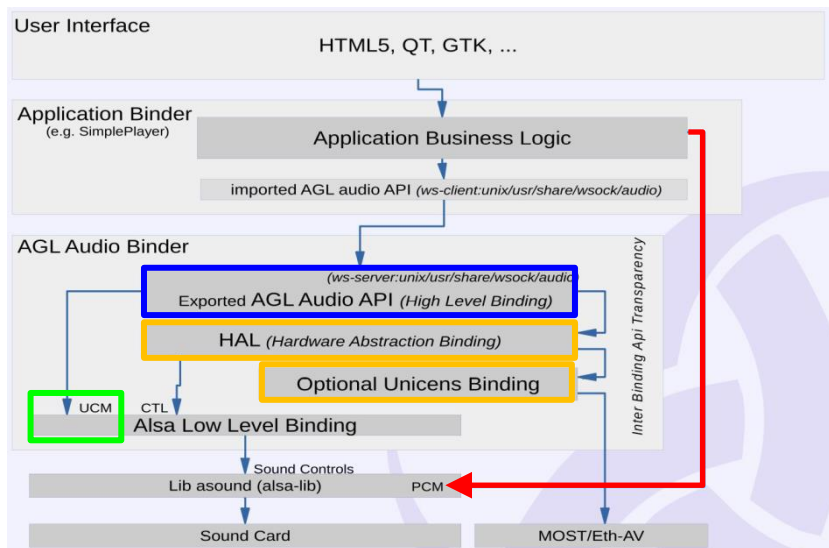

There is no big deference between AAAA and GAM in requirement point of view

### Architecture point of view

## Architecture point of view

|                | AAAA                                                                                    | GAM                                                                                           |
|----------------|-----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| Interface      | High level Binding                                                                      | Command plugin                                                                                |
| Policy         | ALSA UCM + ???                                                                          | Controller plugin                                                                             |
| Adaptation     | HAL, Optional Unicens Binding<br>Dedicated plug-in development is required for external | Routing plugin ALSA and MOST/Eth-AV<br>Dedicated plug-in development is required for external |
| Play streaming | App -> ALSA                                                                             | App -> ALSA                                                                                   |

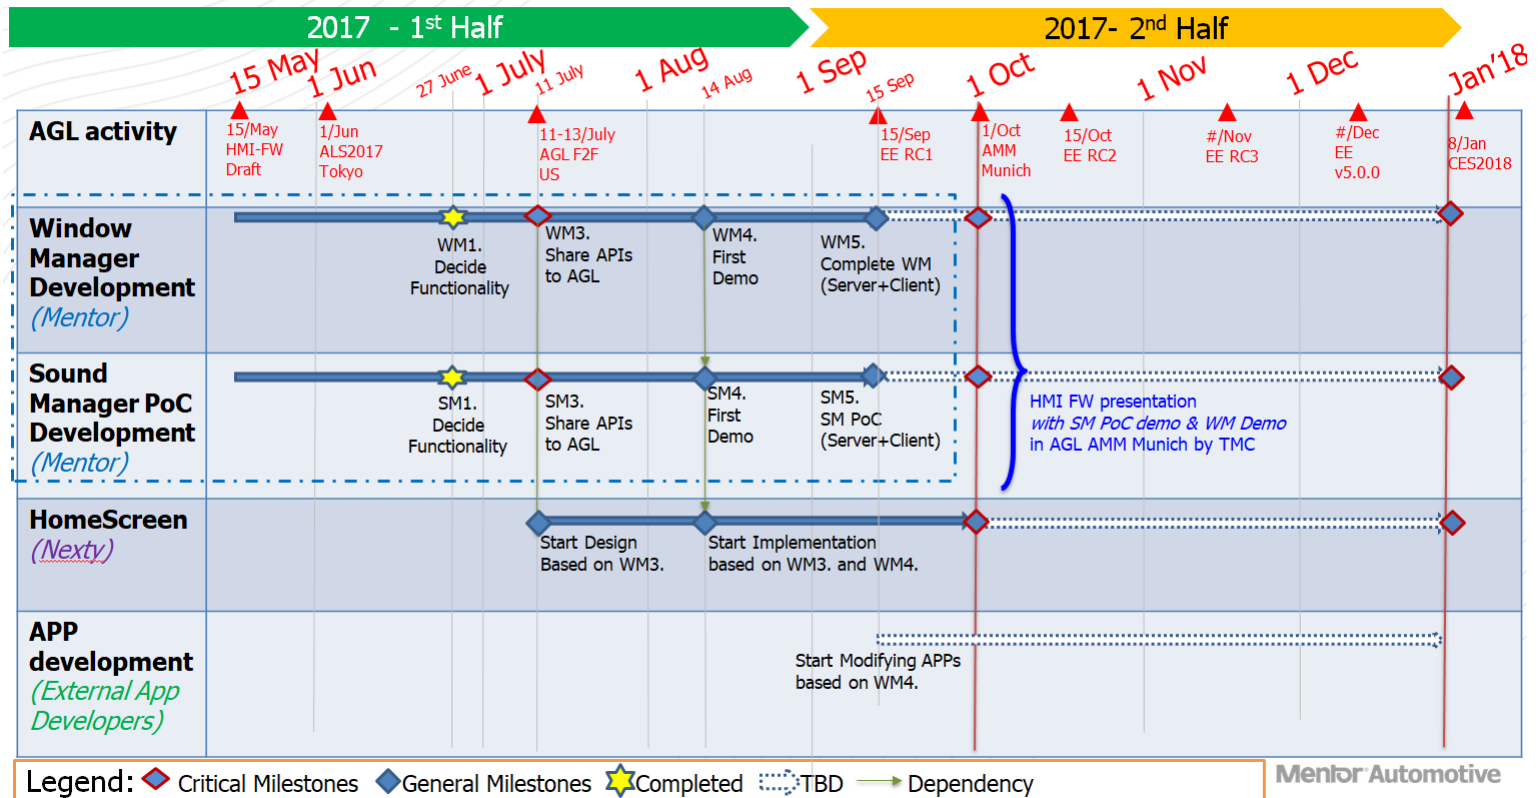

**There is no big deference in architecture point of view.  
Complexity of both is not different**

- **We can realize requirements whichever we choose AAAA or GAM**
  - ◆ There is no big difference between AAAA and GAM in requirement and architecture point of view.
  - ◆ Realization with AAAA has already been realized by GAM.
  
- **I suggest using GAM for sound policy management because:**
  - ◆ **In order to develop sound management of AGL earlier**, it is better to use existing software.
    - GAM is already integrated in AGL
    - Interface and sequence of GAM are already specified and published.
    - GAM has been already evaluated in the market.
  - ◆ **We should focus on integrating new technologies** (e.g. UNICENS, CAN communication or something) to sound management of AGL, rather than **implementing new back end of sound management.**
  
- **We already started PoC development to apply GAM to Binder**

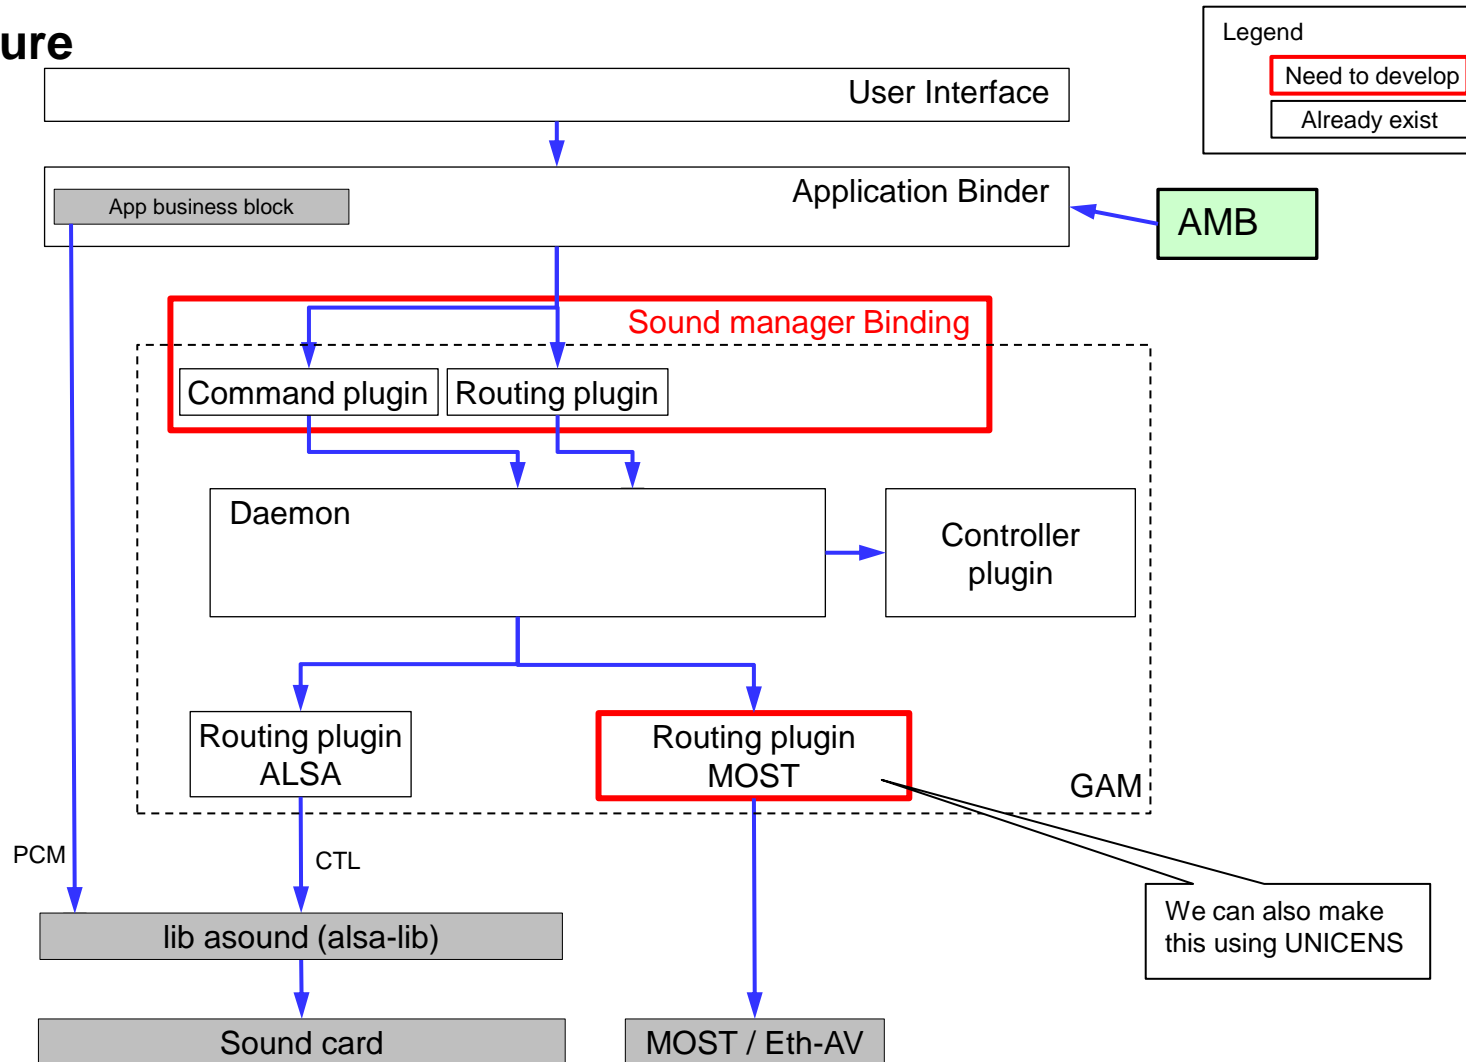

## PoC

- ◆ For CES2018, we are developing sound manager PoC with TOYOTA.
- ◆ Schedule

### TOYOTA AGL HMI FW development – TMC CY2017 roadmap

## Architecture

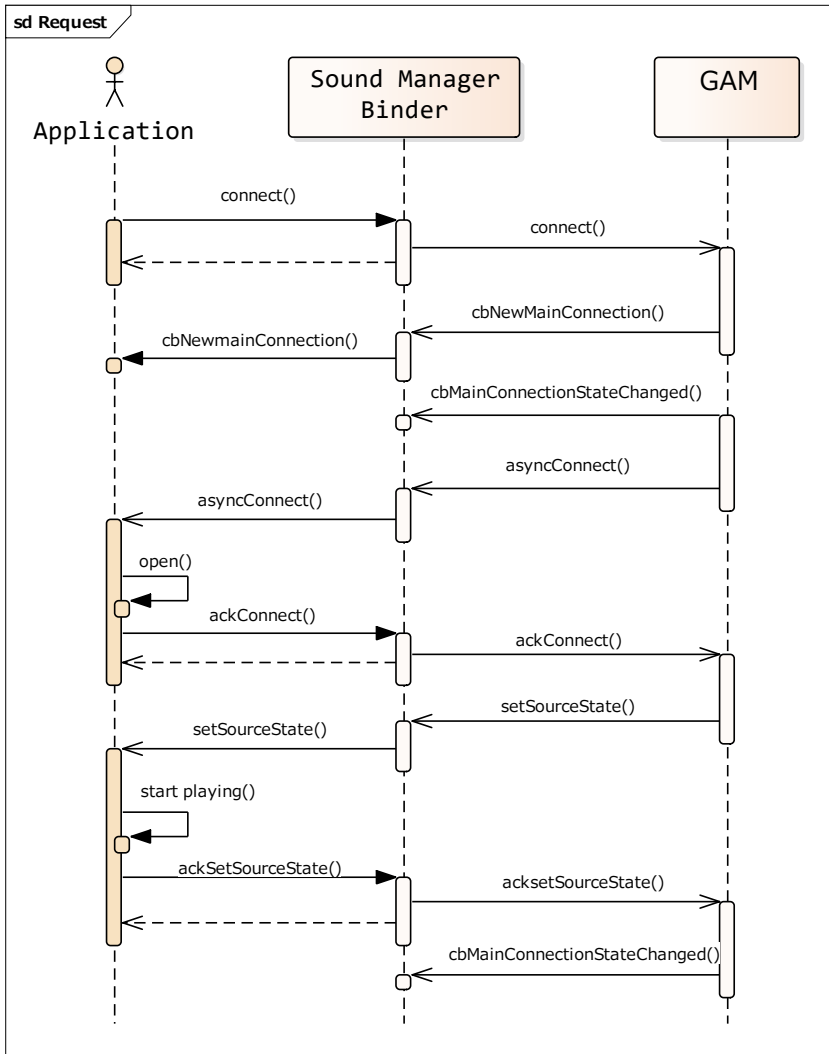

## ■ Interface List

| #  | Interface                                                                 |                    |
|----|---------------------------------------------------------------------------|--------------------|
| 1  | connect (sourceID, sinkID, &mainConnectionID)                             | For command plugin |
| 2  | disconnect (mainConnectionID)                                             |                    |
| 3  | setVolume (sinkID, volume)                                                |                    |
| 4  | volumeStep (sinkID, volumeStep)                                           |                    |
| 5  | setSinkMuteState (sinkID, muteState)                                      |                    |
| 6  | getVolume (sinkID, &mainVolume)                                           |                    |
| 7  | getListMainConnections (&listConnections)                                 |                    |
| 8  | cbNewMainConnection ( mainConnection)                                     |                    |
| 9  | cbRemovedMainConnection (mainConnectionID)                                |                    |
| 10 | cbMainConnectionStateChanged (mainConnectionID, connectionState)          |                    |
| 11 | cbVolumeChanged (sinkID, volume)                                          |                    |
| 12 | cbSinkMuteStateChanged (sinkID, muteState)                                |                    |
| 13 | cbNewSource(source)                                                       |                    |
| 14 | cbNewSink(sink)                                                           |                    |
| 1  | asyncAbort (&handle)                                                      | For routing plugin |
| 2  | asyncConnect (&handle, &connectionID, sourceID, sinkID, connectionFormat) |                    |
| 3  | asyncDisconnect (&handle, connectionID)                                   |                    |
| 4  | asyncSetSinkVolume (&handle, sinkID, volume, ramp, time)                  |                    |
| 5  | asyncSetSourceState (&handle, sourceID, state)                            |                    |
| 6  | ackConnect (handle, connectionID, error)                                  |                    |
| 7  | ackDisconnect (handle, connectionID, error)                               |                    |
| 8  | registerSink (&sinkData, &sinkID)                                         |                    |
| 10 | registerSource (&sourceData, &sourceID)                                   |                    |
| 12 | hookInterruptStatusChange (sourceID, interruptState)                      |                    |
| 13 | hookSourceAvailablityStatusChange (sourceID, &availability)               |                    |
| 14 | ackSetVolumes (handle, &listvolumes, error)                               |                    |

## Sequence

## Sequence

**EOF**

### ■ There are major 4 patterns of arbitration(policy) in automotive

1. The latter source win  
Discards the former source and output the latter source.
2. The latter source win and the former source pause  
Pauses the former source and output the latter.
3. The latter loose  
Continues former source and discards the latter source.
4. The latter source is put on hold  
Continues former source and puts latter source on hold

**Queuing management is required**
